1 Testing Single Case MMR Formulas

1.1 Typical Cases

For testing typical cases we first create data in which both the sufficient term and the outcome are above 0.5. We first create three vectors representing a focal conjunct fct , a complementary conjunct cct , and an outcome yt which take values from 0.6 to 1 in increments of 0.1. We then create a dataframe hd containing all possible combinations between these values, which we subsequently subset for showing only cases above the diagonal ($st \leq yt$) and into two ranks (Rank1: $fct \leq cct$; Rank 2: $fct > cct$).

```
# Typical cases: Filter: S > 0.5 & Y > 0.5 (S- sufficient term, Y- outcome)

fct <- round(seq(0.6, 1, 0.1), digits = 1) #Focal Conjunct
cct <- round(seq(0.6, 1, 0.1), digits = 1) #Complementary Conjunct
yt <- round(seq(0.6, 1, 0.1), digits = 1) #Outcome
hd <- expand.grid(fct, cct, yt)
colnames(hd) <- c("fct", "cct", "yt")
hd$st <- pmin(hd$fct, hd$cct)
hd[, 1:4] <- round(hd[, 1:4], digits = 1)

# Add columns with values in the formulas:

hd$f8a <- round(with(hd, (abs(yt - st) + (1 - st))), digits = 2)
hd$f8laba <- as.character(hd$f8a)
hd$f8a <- round(hd$f8a, digits = 2)
```

```
### Rank 1:
#####
hd1 <- subset(hd, (fct <= cct) & (st <= yt))
```

```
### Rank 2:
#####
hd2 <- subset(hd, (fct > cct) & (st <= yt))
```

Figure 1 provides the formula test for the typical cases we created located in Rank 1. The complementary conjunct cct is held constant at 1, the focal conjunct is varying from left to right, while the outcome yt is varying from bottom to the top. We can see that as membership in the focal conjunct increases (which since $fct \leq cct$ provides the membership value in the sufficient term as well), the formula value decreases respecting the principle of large membership in the sufficient term. Additionally, as the cases get closer to the diagonal and, thus, the distance between the focal conjunct and the outcome gets smaller, the

Figure 1: Typical Cases Test Rank 1

formula values also get smaller. The best possible typical case is the one in the far upper right corner with formula value 0.

Figure 2 provides the formula test for typical cases in Rank 2, which should be taken into consideration only after looking at typical cases in Rank 1, as a second best option. Since for these cases the membership in the sufficient term is given by the complementary conjunct cct, which is fixed at 0.6, cases are all situated in the left part of the upper right quadrant. Formula values drop as cases approach the diagonal, however they don't change in between values of the focal conjunct since these case in Rank 2 are not defined by this.

Figure 2: Typical Cases Test Rank 2

1.2 Deviant Consistency Cases

For producing and testing deviant consistency cases in kind, which are members of the sufficient term, but not of the outcome, we create data in which the sufficient term sdc is above 0.5, but the outcome yc is below 0.5. Figure 3 provides a test for all the possible combinations of sufficient term membership values and outcome membership values created. We can see that as membership in the sufficient term increases (cases more towards the right of the plot), formula values decrease. Additionally, as the distance between membership in the term and membership in the outcome becomes larger (cases further from the diagonal), the formula value becomes smaller, with the best possible case being intuitively located in the lower right corner.

Figure 3: Deviant Consistency Cases

```
# Filter: S > 0.5 & Y < 0.5 (S- sufficient term, Y- outcome)

sdc <- round(seq(0.6, 1, 0.1), digits = 1) #Sufficient Term
ydc <- round(seq(0, 0.4, 0.1), digits = 1) #Outcome
hd <- expand.grid(sdc, ydc)
colnames(hd) <- c("sdc", "ydc")
hd[, 1:2] <- round(hd[, 1:2], digits = 1)

# Add columns with values in the formulas:

hd$f8a <- round(with(hd, ((1 - (sdc - ydc)) + (1 - sdc))), digits = 2)

hd$f8laba <- as.character(hd$f8a)
hd$f8a <- round(hd$f8a, digits = 2)
```

1.3 Deviant Coverage Cases

Deviant coverage cases are situated in the upper left quadrant of an xy plot for sufficiency and therefore for producing them we create data in which membership in the outcome *ydcv* is above 0.5 and membership in the solution formula is below 0.5. Additionally, since the goal of analysing these cases is to identify an entire missing conjunction, membership in the truth table row that the case belongs to *ttcv* also needs to be produced. Figure 4 tests the formula for these cases using all the possible combinations between sufficient solution membership values, outcome membership values, and truth table membership values. Since the membership in the sufficient solution does not enter the calculation of the formula, we can see that values on the same row (equal outcome membership) in the same plot (equal truth table membership) stay the same. However, as truth table row membership increases, and we move from one plot to another, formula values decrease. Additionally, within the same plot, formula values are smaller as the truth table membership is more similar to the outcome membership.

```
# Filter: (F < 0.5) & (Y > 0.5) (F- sufficient formula, Y- outcome)

# NB: This test is quite hard to do and visualize, because we are working
# with both sufficient formula values and TT values

ydcv <- round(seq(0.6, 1, 0.1), digits = 1) #Outcome
fdcvcv <- round(seq(0, 0.4, 0.1), digits = 1) #Sufficient formula
ttcv <- round(seq(0.6, 1, 0.1), digits = 1) #Truth table membership
hd <- expand.grid(fdcvcv, ydcv, ttcv)
colnames(hd) <- c("fdcvcv", "ydcv", "ttcv")
hd[, 1:3] <- round(hd[, 1:3], digits = 1)

# Add columns with values in the formulas:

hd$f8a <- round(with(hd, (abs(ydcv - ttcv)) + (1 - ttcv)), digits = 2)
hd$f8laba <- as.character(hd$f8a)
hd$f8a <- round(hd$f8a, digits = 2)
```

2 Testing Comparative MMR Formulas

2.1 Typical - IIR Cases

For comparing typical and IIR cases we create typical cases as explained above. For testing comparisons in the first 6 Ranks, we create IIR cases that have a focal conjunct *fci* lower than 0.5, a complementary conjunct *cci* taking any values between 0 and 1 (in increments of 0.1), and an outcome *yi* of lower than

Figure 4: Deviant Coverage Cases

0.5. We then create a dataframe `hd` with all the possible combinations between the typical cases' membership values and IIR cases' values.

```
fct <- round(seq(0.6, 1, 0.1), digits = 1) #Focal Conjunct Typical
cct <- round(seq(0.6, 1, 0.1), digits = 1) #Complementary Conjunct
                                     #Typical
yt <- round(seq(0.6, 1, 0.1), digits = 1) #Outcome Typical
fci <- round(seq(0, 0.4, 0.1), digits = 1) #Focal Conjunct
cci <- round(seq(0, 1, 0.1), digits = 1) #Complementary Conjunct IIR
yi <- round(seq(0, 0.4, 0.1), digits = 1) #Outcome IIR
hd <- expand.grid(fct, cct, yt, fci, cci, yi)
colnames(hd) <- c("fct", "cct", "yt", "fci", "cci", "yi")
hd[,1:6] <- round(hd[,1:6], digits = 1)
```

```

# Add columns with values in the formulas:

hd$f8a <- round(with(hd, ((1-(fct-fci))+ #big diff. in FC
                      (1-(yt-yi))+ #big diff in Y
                      abs(cct-cci)+ #small diff in complementary conj.
                      2*abs(yt-pmin(fct,cct))+
                      2*abs(yi-pmin(fci,cci))))
              , digits = 2)

hd$f8laba <- as.character(hd$f8a)

# RANK 1:FCT<=CCT, CCI>0.5, FCI<=CCI
# RANK 2: FCT<=CCT, CCI<0.5, , FCI<=CCI
# RANK 3:FCT<=CCT, FCI < 0.5 & CCI < 0.5 & CCI <= FCI
# (they are all above the diagonal as CCI is providing the min
# for this rank and it is set to 0)
# RANK 4: FCT>CCT, CCI>0.5 , FCI <= CCI
# RANK 5: FCT>CCT, CCI<0.5, , FCI <= CCI

# NB. For cases in this rank, while CCI is held constant,
# CCT is moving (compared to FCT as for the other).
# Since CCT is moving and CCI is constant,
# and YT is moving and YI is constant,
# these two distances cancel each other out.

# For exemplification look at the subseted dataframes that
# show how the two principle cancel
# each other out and the graph is not able to capture this:
# subtest1 <- subset(hd, (fci == c(0.3)) & (yi == c(0.4)) &
#                   # (fct == 1) & (cci == 0.4) & (cct <= yt))
# View(subtest1)

# RANK 6: FCT>CCT, FCI < 0.5 & CCI < 0.5 & CCI <= FCI
# (all above the diagonal as CCI is the min and set to 0)
# NB. For cases in this rank, CCI is held constant while CCT moving

```

```

# (compared to FCT as for the other ranks).
# Since CCT is moving and CCI is constant,
# and YT is moving and YI is constant,
# these two distances cancel each other out.

# For exemplification look at the subseted dataframes that show how
# the two principle cancel each other out and the graph is
# not able to capture this:

# subtest2 <- subset(hd, (fci == c(0.3)) & (yi == c(0.4)) &
#                       (fct == 1) & (cci == 0) & (cct <= yt))
# View(subtest2)

```

For testing Rank 1 we subset only those typical cases in which the focal conjunct is smaller or equal to the complementary conjunct (therefore providing the membership in the sufficient term), and those IIR cases in which the complementary conjunct is above 0.5 and, subsequently, larger than the focal conjunct. For setting up the test in Figures 5, 6, 7, and 8 we keep membership in the complementary conjunct of the typical and IIR case constant (set at 1), while varying membership of the typical case's focal conjunct and typical case's outcome *within* the same plot, and membership of the IIR case's focal conjunct and IIR case's outcome *between* the plots. Within each plot in the two figures (keeping the IIR case constant) the formula values get smaller as the typical case approaches the diagonal (small corridor for mechanism), as the membership in the typical case focal conjunct increases (making the difference in the focal conjuncts bigger) and as the membership in outcome increases (bigger difference in outcome values). Between the plots, the formula values increase the furthest the IIR case gets from the diagonal (making the corridor for the mechanism larger), the larger its membership in the focal conjunct is (making it close to the focal conjunct value of the typical case) and the larger its membership in the outcome is (making it close to the outcome value of the typical case). Additionally, formula values are symmetrical for IIR cases above and below the diagonal and the best possible case comparison (formula value is 0) is between the extreme lower left corner and the extreme upper right corner.

For testing Rank 2 we subset typical cases in which the focal conjunct is smaller or equal to the complementary conjunct, and IIR cases in which the complementary conjunct is below 0.5, but still larger than the focal conjunct. For setting up the test in Figures 9, 10, 11 and 12 we keep membership in the complementary conjunct of the typical and IIR case constant (set at 1 and 0.4, respectively), while varying membership of the typical case's focal conjunct and typical case's outcome *within* the same plot, and membership of the IIR case's focal conjunct and IIR case's outcome *between* the plots. Test results are the same as for Rank 1, within each plot (keeping the IIR case constant) formula values getting smaller as the typical case approaches the diagonal and as the membership in the typical case focal conjunct and outcome increase.

Figure 5: Typical-IIR Rank 1 with IIR above diagonal

Again, between the plots, the formula values increase the furthest the IIR case gets from the diagonal and the larger its membership in the focal conjunct and outcome is.

Pairs in Rank 3 consist of typical cases in which the focal conjunct is smaller or equal to the complementary conjunct, and IIR cases in which the complementary conjunct is below 0.5 and smaller than the focal conjunct. Therefore, xy plots will not be able to reflect changes in the focal conjunct value for the IIR case, as the sufficient term membership is given by the complementary conjunct. Figures 13 and 14 present the test in which typical complementary conjunct is set to 1 and IIR complementary conjunct is set to 0. *Within* the same plot (keeping the IIR case constant) formula values are smaller as the typical case approaches the diagonal, as the membership in the typical case focal conjunct increases and as the membership in outcome increases. *Between* plots the formula

Figure 6: Typical-IIR Rank 1 with IIR above diagonal

values increase the furthest the IIR case gets from the diagonal. Additionally, the formula values also increase as the membership values of the IIR case in the focal conjunct increases, which can be noticed between plots where the IIR case is located in the same spot, but the fci value is different.

For pairs in Rank 4 typical cases have focal conjuncts larger than their complementary conjuncts, while IIR cases have complementary conjunct above 0.5 and, subsequently, larger than their focal conjuncts. Since the sufficient term membership of the typical cases is given by the complementary conjuncts, xy plots between the sufficient term and the outcome will not be able to reflect changes in the focal conjunct value for these cases. For the test in Figures 15, 16, 17, and 18 the typical focal conjunct is set to 1 and the IIR complementary conjunct is set to 1. *Within* the same plot (keeping the IIR case constant) formula values are smaller as the typical case approaches the diagonal (respecting the

Figure 7: Typical-IIR Rank 1 with IIR below diagonal

principle of small corridor for the mechanism), as the membership in outcome increases (bigger difference in outcome values) and as the membership in the complementary conjunct approaches 1, the value of the IIR complementary conjunct. *Between* plots the formula values increase the furthest the IIR case gets from the diagonal and as the membership values of the IIR case in the focal conjunct increases.

Rank 5 consists of typical cases that have focal conjuncts larger than their complementary conjuncts and IIR cases that have complementary conjuncts below 0.5, but still larger than their focal conjuncts. The test for these cases is set just like the test for cases in Rank 4, with the sole difference that now the IIR case membership in the complementary conjunct is set to 0.4. The results in Figures 19, 20, 21, and 22 show that *within* the same plot (keeping the IIR case constant) formula values are smaller as the typical case approaches the diagonal

Figure 8: Typical-IIR Rank 1 with IIR below diagonal

(respecting the principle of small corridor for the mechanism). However, cases with the same distance to the diagonal have the same value, as two principles cancel out each other. Formula values increase as the membership in outcome increases (bigger difference in outcome values), but decrease as the membership in the complementary conjunct are lower and approach 0.4, the value of the IIR complementary conjunct.

Pairs in Rank 6 have typical cases with focal conjuncts larger than their complementary conjuncts and IIR cases with complementary conjuncts smaller than their focal conjuncts, which are below 0.5. The test in Figures 23, 24, and 25 has the typical focal conjunct set to 1 and the IIR complementary conjunct set to 0, which keeps all the IIR cases chosen for the test above the diagonal and on the same vertical line. As for Rank 5, results show that formula values decrease within plots, as typical cases approach the diagonal, but stay

Figure 9: Typical-IIR Rank 2 with IIR above diagonal

the same for those with the same distance to it as two principles cancel out (big difference in outcome, but small difference in complementary conjunct). Formula values increase as IIR cases get further from the diagonal, as they have a larger membership in the outcome, and as their membership in the focal conjunct increases (which is not reflected in the location of the dot identifying the case).

Lastly, pairs in Ranks 7 and 8 have IIR cases with focal conjuncts larger than 0.5 and complementary conjuncts smaller than 0.5, which for the purpose of these test we will set to 0. Typical cases in Rank 7 have focal conjuncts smaller than their complementary conjuncts, which for testing we set to 1. In Figures 26, 27, and 28, formula values decrease within plots, as typical cases approach the diagonal, as they have a larger membership in the outcome, and as they have a larger membership in the focal conjunct. Formula values increase between plots

Figure 10: Typical-IIR Rank 2 with IIR above diagonal

as IIR cases get further from the diagonal, as their membership in the outcome increases, and as their membership in the focal conjunct increases (which is not noticeable in the location of the dots). Alternatively, typical cases in Rank 8 have focal conjuncts larger than their complementary conjuncts, and therefore we set fct to 1. In Figures 29, 30, and 31 formula values decrease within plots as typical cases approach the diagonal, but stay the same at the same distance due to principles cancelling out (big difference in the outcome, small difference in the complementary conjuncts). Formula values increase between plots in the same manner as for Rank 7.

```
# For the last two ranks we need to create data
# that has CCI < 0.5 and FCI > 0.5:
```

Figure 11: Typical-IIR Rank 2 with IIR below diagonal

```
fct <- round(seq(0.6, 1, 0.1), digits = 1)
cct <- round(seq(0.6, 1, 0.1), digits = 1)
yt <- round(seq(0.6, 1, 0.1), digits = 1)
fci <- round(seq(0.6, 1, 0.1), digits = 1)
cci <- round(seq(0, 0.4, 0.1), digits = 1)
yi <- round(seq(0, 0.4, 0.1), digits = 1)
hd2 <- expand.grid(fct, cct, yt, fci, cci, yi)
colnames(hd2) <- c("fct", "cct", "yt", "fci", "cci", "yi")
hd2[,1:6] <- round(hd2[,1:6], digits = 1)

# Add columns with values in the formulas:

hd2$f8a <- round(with(hd2, ((1-(fct-fci))+ #big diff. in FC
```

Figure 12: Typical-IIR Rank 2 with IIR below diagonal

```

(1-(yt-yi))+ #big diff in Y
abs(cct-cci)+ #small diff in complementary conj.
2*abs(yt-pmin(fct,cct))+
2*abs(yi-pmin(fci,cci)))
#small corridor for mechanism
, digits = 2)

hd2$f81aba <- as.character(hd2$f8a)

# Rank 7 (FCT<=CCT, CCI <0.5, FCI > 0.5):

# Rank 8 (FCT>CCT, CCI <0.5, FCI > 0.5):

```

```
# NB. For cases in this rank, while CCI is
# held constant while CCT moving
# (compared to FCT as for the other ranks).
# Since CCT is moving and CCI is constant, and
# YT is moving and YI is constant,
# these two distances cancel each other out.
```

2.2 Typical - Typical Cases

For testing pairs of typical and typical cases we create data for two typical cases in which the focal conjunct *fct*, the complementary conjunct *cct*, and an outcome *yt* are all above 0.5. Two filters are initially applied to the dataframe

Figure 14: Typical-IIR Rank 3

so created: firstly, only cases above the diagonal are selected ($st \leq yt$), and secondly, the first case needs to be more typical than the second case. After the dataset is subsetting, the remaining typical cases are divided into two types as before (Rank1: $fct \leq cct$; Rank 2: $fct > cct$) which create four possible combinations or pair ranks.

```
fct1 <- round(seq(0.6, 1, 0.1), digits = 1) # Focal Conjunct Case 1
cct1 <- round(seq(0.6, 1, 0.1), digits = 1) # Complementary Conj. Case1
yt1 <- round(seq(0.6, 1, 0.1), digits = 1) # Outcome Case 1
fct2 <- round(seq(0.6, 1, 0.1), digits = 1) # Focal Conjunct Case 2
cct2 <- round(seq(0.6, 1, 0.1), digits = 1) # Complementary Conj. Case2
yt2 <- round(seq(0.6, 1, 0.1), digits = 1) # Outcome Case 2
hd <- expand.grid(fct1, cct1, yt1, fct2, cct2, yt2)
```

Figure 15: Typical-IIR Rank 4 with IIR above diagonal

```
colnames(hd) <- c("fct1", "cct1", "yt1", "fct2", "cct2", "yt2")
hd[,1:6] <- round(hd[,1:6], digits = 1)

# Filtering:

# Cases should be above the diagonal:
# (Styp1 <= Ytyp1) & (Styp2 <= Ytyp2)

# Case 1 should be more typical than Case 2:
# ((abs(yt1-pmin(fct1,cct1)) + (1-pmin(fct1,cct1))) <=
# (abs(yt2-pmin(fct2,cct2)) + (1-pmin(fct2,cct2))))
```

Figure 16: Typical-IIR Rank 4 with IIR above diagonal

```

hd <- subset(hd, (pmin(fct1,cct1) <= yt1) & (pmin(fct2,cct2) <= yt2) &
  ((abs(yt1-pmin(fct1,cct1)) + (1-pmin(fct1,cct1))) <=
  (abs(yt2-pmin(fct2,cct2)) + (1-pmin(fct2,cct2)))))

# Add columns with values in the formula:

hd$f8a <- round(with(hd, ((0.5-(fct1-fct2))+ #big diff. in FC
  (0.5-(yt1-yt2))+ #big diff in Y
  abs(cct1-cct2)+ #small diff in complementary conj.
  2*abs(yt1-pmin(fct1,cct1))+
  2*abs(yt2-pmin(fct2,cct2)))))
  #small corridor for mechanism

```

Figure 17: Typical-IIR Rank 4 with IIR below diagonal

```

, digits = 2)
hd$f8a<- round(hd$f8a, digits = 2)
hd$f81aba <- as.character(hd$f8a)

# (RANK 1:FCT1<=CCT1,FCT2<=CCT2):
# (RANK 2:FCT1<=CCT1,FCT2>CCT2):
# (RANK 3:FCT1>CCT1,FCT2<=CCT2):
# (RANK 4:FCT1>CCT1,FCT2>CCT2):

```

In Pair Rank 1, both typical cases have their focal conjunct smaller or equal

Figure 18: Typical-IIR Rank 4 with IIR below diagonal

to the complementary conjunct. As it can be seen in Figures 32 and 33, only cases more typical than the dotted typical case are selected for pairing. Within the same plot formula values are smaller the higher the membership of the more typical case is in the focal conjunct and the outcome, and the closer to the diagonal that case it. Between plots, formula values get smaller the closer to the diagonal the dotted plot is and the smallest its membership is in the focal conjunct and the outcome.

In Pair Rank 2, one typical cases has the focal conjunct smaller or equal to the complementary conjunct, while the other one does not. Within the same plot in Figure 34 and Figure 34, results are the same as for Pair Rank 1 with formula values decreasing the higher the membership of the more typical case is in the focal conjunct and the outcome, and the closer to the diagonal that case it. Between plots, formula values get smaller the closer to the diagonal

Figure 19: Typical-IIR Rank 5 with IIR above diagonal

the dotted plot is, the smallest its membership is in the the outcome, and the smallest the focal conjunct is. However, the last difference cannot be seen in the position of the dotted case in the xy plot, as it is the complementary conjunct providing the membership in the sufficient term in this case ($cct2 \uparrow fct2$).

Plots of the cases in Pair Rank 3 (Figures 36, 37, and 38) are less intuitive to interpret as it is the more typical cases that has the focal conjunct higher than the complementary conjunct. For setting up this test, the dotted case is the more typical one with smaller distance between the sufficient term and y and larger membership in the focal conjunct. Within the same plot, the formula gets smaller the further away from the diagonal the second typical case gets and the bigger the difference in the focal conjunct value gets. Between plots, formula values get smaller the closer to the diagonal the dotted plot is and the bigger the difference in the focal conjunct value gets. Cases in Pair Rank 4 function

Figure 20: Typical-IIR Rank 5 with IIR above diagonal

in a similar manner, with the exception that Typical Case 2's membership in the sufficient term is defined by the complementary conjunct and therefore differences between focal conjuncts cannot be spotted in the same plot.

2.3 Typical - Deviant Consistency Cases

Figures 42 and 43 show the test for pairing typical case and deviant consistency cases in kind. Within the same plot we see that the bigger the difference in outcome values between the typical case and the deviant case, the smaller the formula values is. However, deviant consistency cases on the same horizontal line have the same formula values. This is because two of the principles implemented cancel each other out when keeping the typical case static: the larger the membership of the deviant consistency case in the sufficient term,

Figure 21: Typical-IIR Rank 5 with IIR below diagonal

the larger also the difference to the term membership of the static typical case. Nevertheless, looking between plots, we can see that formula values drop as the typical case term membership is larger and as the difference to the deviant case term membership is smaller.

```

st <- round(seq(0.6, 1, 0.1), digits = 1) #Sufficient Term Typical
yt <- round(seq(0.6, 1, 0.1), digits = 1) #Outcome Typical
sc <- round(seq(0.6, 1, 0.1), digits = 1) #Sufficient Term DCN
yc <- round(seq(0, 0.4, 0.1), digits = 1) #Outcome DCN

hd <- expand.grid(st, yt, sc, yc)
colnames(hd) <- c("st", "yt", "sc", "yc")
hd[,1:4] <- round(hd[,1:4], digits = 1)

```

Figure 22: Typical-IIR Rank 5 with IIR below diagonal

```
# Add columns with values in the formulas:

hd$f8a <- round(with(hd, ((1-(yt-yc))+ #big diff in Y
                        abs(st-sc)+ #small diff in s.
                        (1-st)+
                        (1-sc))) #large s
               , digits = 2)

hd$f8laba <- as.character(hd$f8a)
hd$f8a <- round(hd$f8a, digits = 2)
```

Figure 23: Typical-IIR Rank 6

2.4 Deviant Coverage - IIR Cases

The last relevant comparison discussed in the paper is the one between deviant coverage cases and IIR cases in the same truth table row. Since the formula for this comparison is mainly based on truth table membership, the xy plots between the sufficient formula and the outcome will not be able to reflect some of the principles implemented. Figures 44, 45, 46, and 47 show the test for these pairs keeping sufficient solution membership of the deviant coverage term fixed at 0 and 0.4, and the truth table row membership of the IIR case at 1. Within the same plot, as it is only the difference in outcome membership that is relevant to the formula, we can see that the bigger this gets, the smaller formula values become, with cases on the same horizontal line having the same formula value. Between plots, we notice that formula values also get smaller as the membership of the deviant coverage case in the outcome increases and as the truth

Figure 24: Typical-IIR Rank 6

table membership of this case increases. However, the last difference cannot be spotted by moves in the positions of the dot reflecting the deviant coverage case, but rather by looking at identical plots with respect to its position, but different truth table membership values.

```
# Assume they all are in the same TT Row:
# DCV: (F<0.5) & (Y>0.5) & (TT<=Y)
# IIR: (S<0.5) & (Y<0.5)

fc <- round(seq(0, 0.4, 0.1), digits = 1) #Formula membership DCV
yc <- round(seq(0.6, 1, 0.1), digits = 1) #Outcome DCV
